

A rural landscape at sunset or sunrise. In the foreground, a tractor is visible, and a herd of cattle is grazing in the distance. The sky is filled with soft, golden light, and the overall scene is peaceful and agricultural.

# Commissioning and Managing Agriculture Inventory Research Projects

Commissioning and designing research projects to maximise the chances of new research being incorporated in GHG inventories

Joel Gibbs – Ministry for Primary Industries, New Zealand

# Contents

- Introduction
- Identifying/prioritising research topics
- Commissioning and design
- Implementation of new methods and emission factors in inventories
- Examples

# Introduction

- Overall purpose of commissioning research and incorporating this research into the inventory is to improve accuracy of emissions estimates, or to get a better understanding of emissions uncertainty
- The notes in this presentation are based on my experiences only – others may have their own observations based on their experience and the situations with their inventories and available resources

# Identifying/prioritising research topics

- Existing inventory analysis(i.e. key category analysis, expert review recommendations and main sources of uncertainty)
- Workshop/conference with researchers and scientists to identify new research
- How long since research in a particular area was done

# Procurement design

- Important to have clear, unambiguous requirements in commissioning research
- Making sure the intended outcomes of the research will have clear recommendations for inventory improvements (Unless the work is intended to be exploratory).

# Procurement design (continued)

Worth considering:

- setting aside resource for independent peer review, particularly if a significant change is being proposed.
- asking researchers to submit their research to a Journal and;
- if EF's generated, submitting these to relevant databases (i.e. IPCC EFDB, DATAMAN, MELS, N2O EF Database)

**HIGHLIGHTS**

- Current NZ-specific N<sub>2</sub>O emission factors (EF<sub>i</sub>) are 1.02 (urine) and 0.253 (dung).
- A meta-analysis of 1217 EF<sub>i</sub> data representative of livestock grazing was completed.
- The analysis showed that the dung EF<sub>i</sub> values should be reduced to 0.128.
- Urine EF<sub>i</sub> values ranged from 0.082 to 0.982, based on livestock type and topography.
- We recommend the revised values are employed in NZ's national N<sub>2</sub>O inventory.

**GRAPHICAL ABSTRACT**

The graphical abstract is a 3D landscape diagram showing different topographies: flatland, medium slope, and steep slope. It illustrates the current and revised N<sub>2</sub>O emission factors (EF<sub>i</sub>) for urine and dung from different livestock types. The current EF<sub>i</sub> for urine is 1.02 and for dung is 0.253. The revised EF<sub>i</sub> for urine is 0.128 and for dung is 0.128. The diagram shows that the revised EF<sub>i</sub> values are significantly lower than the current values, particularly for urine. The diagram also shows that the revised EF<sub>i</sub> values are based on livestock type and topography. The diagram includes a table with the following data:

Category	Current EFi	Revised EFi
Urine (All livestock)	1.02	0.128
Dung (All livestock)	0.253	0.128

**ABSTRACT**

Globally, animal excreta (dung and urine) deposition onto grazed pastures represents more than half of anthropogenic nitrous oxide (N<sub>2</sub>O) emissions. To account for these emissions, New Zealand currently employs urine and dung emission factor (EF<sub>i</sub>) values of 1.02 and 0.253, respectively, for all livestock. These values are primarily based on field studies conducted on fertile, flatland pastures predominantly used for dairy cattle production but do not consider emissions from hill land pastures primarily used for sheep, deer and non-dairy cattle. The objective of this study was to determine the most suitable urine and dung EF<sub>i</sub> values for dairy cattle, non-dairy cattle, and sheep grazing pastures on different slopes based on a meta-analysis of New Zealand EF<sub>i</sub> studies. As none of the studies included deer excreta, deer EF<sub>i</sub> values were estimated from cattle and sheep values. The analysis revealed that a single dung EF<sub>i</sub> value should be maintained, although the value should be reduced from 0.253 to 0.128. Furthermore, urine EF<sub>i</sub> should be disaggregated by livestock type (cattle > sheep) and topography (flatland and low sloping hill country > medium and steep sloping hill country), with EF<sub>i</sub> values ranging from 0.082 (sheep urine on medium and steep slopes) to 0.982 (dairy cattle on flatland and low slopes). While the mechanism(s) causing differences in urine EF<sub>i</sub> values for sheep and cattle are unknown, the 'slope effect' on urine EF<sub>i</sub> is partly due to differences in soil chemical and physical characteristics, which influence soil microbial processes on the different slope classes.

# Implementation of new research in inventories

- Significant inventory improvements will be reviewed more thoroughly by ERTs – need to ensure the case for change is justified and backed up by strong evidence
- Worth considering having a group of independent inventory experts to review any inventory change and make recommendations – Audit/paper trail is useful as well

# Research examples

Some examples of inventory research leading to inventory improvements

- More accurate information on the purity of agricultural lime (which affects GHG emissions) - research commissioned in 2020, completed in 2021, and incorporated into the New Zealand inventory in 2022
- N<sub>2</sub>O emission factors for different hill slopes – 3 separate pieces of research over 6 years

Some research projects can be incorporated directly into inventories, while other improvements require multiple research projects, which might be both field or desk based

# Key messages

- Important to have clear, unambiguous requirements in commissioning research
- Make sure the intended outcomes of the research will have clear inventory recommendations, and ensure these are clearly stated in the contract
- Important to set aside resource for independent peer review, particularly if a significant change is being proposed
- Some research projects can be incorporated directly into inventories, while other improvements require multiple research projects, which might be both field or desk based
